Abstract

The National Academies of Science, Engineering and Medicine (NAS) conducts Decadal Surveys which NASA uses to prioritize budget and future strategy. This paper investigates how science plans at NASA align with scientific community consensus identified in the Decadal Surveys. We used Natural Language Processing (NLP) to compare these surveys and NASA science plans, by highlighting similarities and discrepancies. We created a baseline of evidence based on a group of 4 Decadal Surveys from 2001 to 2007 and then we measured the similarities and dissimilarities between NASA science plans against this baseline. Alignment between science plans with baseline Decadal Surveys is shown to decrease over time, which can indicate a potential decreasing effect of earlier decadal surveys on later science plans, a shift in scientific consensus, or a shift in operational realities.

Keywords: NASA science policy, decadal surveys, policy alignment, natural language processing, context embeddings, semantic similarity, science planning, space science

1. Introduction and Literature Review

NASA alignment with scientific community interests in science discovery is of major importance to the scientific community. Still, limited research has

*Corresponding author
Email address: rwitt4@gmu.edu (Richard Witt)

been conducted on this alignment with only two studies seeking to identify this relationship [1] [2]. Further, these studies focus solely on Astronomy and Astrophysics. We aim to observe project alignment across all NASA Science Mission Directorates using natural language processing techniques.

Creating a strategic plan for United States science discovery is a multi-agency, multi-year planning process. Two key corpora result from this planning process. The first corpus is U.S. National Academies of Science, Engineering, and Medicine (Academies) (NAS), which created the Decadal Surveys. The second corpus is composed of NASA strategic plans, and NASA Science Mission Directorate science plans. In this paper we reefer to strategic and science plans collectively as NASA plans. NASA plans are used to define NASA project priorities while Decadal Surveys are used to identify scientific community interests.

1.1. Decadal Surveys

Decadal surveys are a strategic guide for the planning and execution of United States investments in Science and Technology[3]. The purpose of decadal surveys is to reach consensus on science priorities for the next decade while aligning with the executive branch initiatives and adhering to fiscal budget constraints. The Space Studies Board at the Academies reviewed lessons learned and best practices for prior surveys in 2015. The bulk of this section relies on this work except where otherwise cited [3].

Decadal Surveys are important to the entire scientific community. Survey chairs and committee members are accomplished scientists and engineers who are active leaders in their field from top institutions and universities in the United States. A review of decadal survey committee and panel members reads like a who's who of science and engineering. NASA and National Science Foundation (NSF) officials refer to the Decadal Survey recommendations as a blueprint or guidebook and individual research scientists refer to the surveys as a "sword and shield": a sword for wining approval and shield against cancellation of federally funded programs. Two independent studies of surveys in 2011 [1] and 2023 [2] both found that around 60% of projects identified in the Decadal Surveys are funded within 15 years of survey publication.

Stakeholders in the decadal surveys include many U.S. government agencies, departments, and foundations. NASA's Science Mission Directorate (SMD) is a common sponsor of the decadal surveys along with the NSF. Additional science community stakeholders in the decadal surveys include

DOE, NOAA, and USGS. Congress, the Office fo Management and Budget, and other executive branch agencies use Decadal Surveys to evaluate budgetary plans.

This multi-agency, multi-stakeholder arrangement, as well as the considerable workload, high standards, and complexity of the task causes the process of conducting decadal surveys to be long and complex. The process starts with the Academies creating a statement of task for the committee to respond to. The Academies' Space Studies Board works with other standing committees at the Academies to select a survey chair and committee of around 20 members. The survey committee, with help from the Academies staff, organizes panels and working groups by science themes, observational techniques, facilities, or subject. This freedom of organization allows for the culture of the scientific field and preference of the survey organizers to mold the committee. The surveys gather broad community input through public meetings, "white papers", and direct presentations. The panels then create a ranked program of missions and activities based on science and observational capabilities specific to the panels area of responsibility. Panel priorities are then ranked across the field by the survey committee.

Independent reviews ensure scientific and fiscal rigor. Once panels and committees have completed their work, independent cost and risk evaluation is conducted for larger space missions and ground based facilities as mandated by the U.S. Congress [4]. The committee's report also undergoes an independent review to validate that conclusions are supported and documented. The final report takes around 2 years to complete and provides a consensus vision of for its respective field.

Follow-up on decadal surveys requires multi-agency involvement. Once the survey report is published the committee is disbanded. Post report stewardship is conducted by standing committees at the Space Studies Board through periodic reviews, which offer guidance to the agencies on decadal programs. The NASA Advisory Council's Science subcommittees at the Academies follow NASA's progress. A congressionally directed midterm review of decadal surveys focus on agency progress to compare activities with survey science goals is also conducted [5]. The National Science Foundation receives input from the scientific community through proposals to it's various programs. The Department of Energy evaluates progress through extensive internal processes for energy related components of the surveys while independent committees such as the Astrophysics Advisory Committee, provide advisory services on multi-agency projects.

Decadal surveys serve as a national science strategy and are intended to inform science strategy at NASA and other federal agencies.

1.2. NASA Science Strategy

NASA relies heavily on decadal surveys to inform its science strategy. NASA's 2025 Presidents Budget Request states "SMD uses the recommendations of the National Academies' decadal surveys as important inputs in planning and prioritizing the future of its science programs." The same budget references decadal surveys 87 times, demonstrating NASA's focus on the surveys to define science strategy [6].

The decadal surveys are not the only input to NASA science strategy. The Office of the Chief Scientist (OCS) represents all of the scientific endeavors in the agency, ensuring they are aligned with and fulfill the administration's science objectives [7]. International scientific consensus is also important, since two-thirds of SMD missions involve international partnerships [8].

Science strategy is further refined by operational realities. The SMD Large Mission Study (LMS) Report lays out the most current Simplified Project Lifecycle available. This report identifies 7 Project Life-Cycle Phases, three of which occur prior to implementation and are therefore germane to the the project prioritization process. These 3 phases are: *Phase Pre-A: Concept Studies*, *Phase A: Concept and Technology Development*, and *Phase B: Preliminary Design and Technology Completion*. During this process decadal survey recommendations are turned into decisions on mission architectures, preliminary requirements and budget estimates. In the Pre-Phase-A period, missions are not yet projects and focus is on quantifying science vs. cost, exploiting the range of solutions while maintaining dialog with Academy committees to ensure the intent of the decadal survey is honored. Once Key Decision Point-A passed, the concept is identified as executable and continues through the rest of the Concept Maturity Model to eventually become a project once Phase B is completed. [9] [10].

The science strategy that results from this refinement process is defined in the NASA plans that are created. Since a large portion of the plan is natural language text additional processing is needed to extract information which can be measured using numerical methods. This information extraction is the process of creating word embeddings.

1.3. Word and Context Embeddings

Word embeddings are numerical interpretations of words that capture syntactic and semantic meaning for individual words [11], sentences [12], and documents [13]. These numerical interpretations, or word vectors, can be used to understand textual relationships mathematically. In 2013 Word2Vec extended [11] and formalized [14] prior work by Bengio et al. [15].

While early word embeddings were limited to a single global representation for each word the ELMo model [16] used context-dependent inputs to capture meaning across diverse contexts, enabling the model to interpret words with polysemy thus beginning the era of Context Embedding models. BERT [17] added bidirectional encoding, GPT [18] added auto-regression prediction and BART [19] combined these two innovations to increase performance on text generation tasks. Embedding models are used as an unsupervised stage prior to the supervised fine tuning stage for transformer based large language models since their inception [20] and in current state of the art open source models [21].

Our research relies on OpenAI's `text-embedding-ada-002` model due to its favorable performance in document level search [22]. The model was released on December 15, 2022 [23] as closed source. However, on January 24, 2022 OpenAI published Text and Code Embeddings by Contrastive Pre-Training [24] indicating that `text-embedding-ada-002` is likely an evolution of this prior work using a contrastive objective on paired samples with relatedness evaluated using cosine similarity.

1.4. Outline

The remainder of this paper is structured as follows: Section 2 describes the methodology and rationale used to compare project priorities at NASA with scientific consensus using context embeddings. Section 3 details the source documentation used in the analysis. Section 4 provides the analysis and results from the documentation comparison. Finally Section 5 discusses the results and describes potential paths for future work.

2. Methodology and rationale

This analysis followed a methodology adapted from the CRoss Industry Standard Process for Data Mining (CRISP-DM)[25]. The methodology consists of idempotent process steps of Ingest, Prepare, Pre-process, Model, and Validate. This outline is shown in Figure 1.

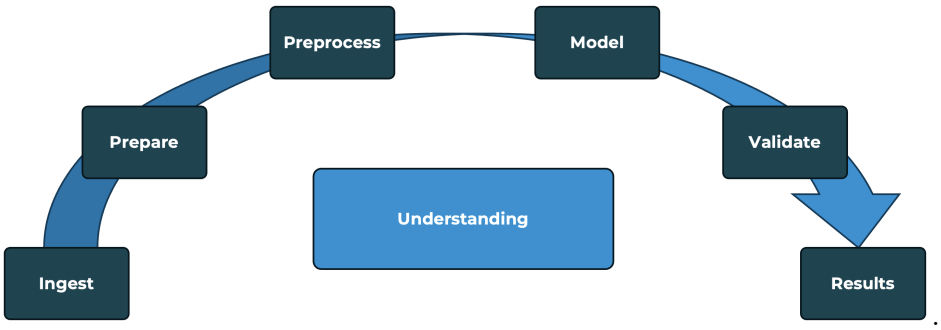

Figure 1: Core Data Science Process

2.1. Ingesting Source Data

Data ingestion was a manual process using file names to embed metadata into the the files. This metadata was then used programmatically in follow on processes. Metadata consists of: publication year, document category, and publication type; these were all encoded into the file names to ensure accurate processing. For information on the specific data used see the Section 3 Data.

Once data is ingested the next step is to prepare the data.

2.2. Preparing the Text

The first step in preparation is to extract the text from the PDF files. We completed this step with `PDFminer` which is a common PDF parser and analyzer[26]. `PDFminer` extracted raw page text which is then cleaned with Python's `re` module which provides support for regular expressions. Regular expressions were used to remove patterns in text such as special characters used in PDF formatting, page numbers, and blank pages. Document metadata, such as year of publication, was then extracted from the file names and stored as metadata with text from each page resulting in a total corpus size of just over 800 pages of NASA science plans and decadal surveys. Each page of clean text with metadata was then stored for further preprocessing with contextual embeddings.

Now that the data is prepared we can preprocess it for our specific analysis.

2.3. Preprocessing with Contextual Embeddings

Once the text is prepared each individual page is turned into a contextual embedding vector with 1536 dimensions using the `text-embedding-ada-002`

model. High dimensional embeddings were chosen to leverage prior studies on document level search [22] and because we speculate that higher dimensionality may better represent the context, semantics, and syntactic meaning in a large chunk of text such as a page of a PDF document.

After preprocessing the data is ready to be modeled.

2.4. Modeling with Contextual Comparison

All contextually embedded pages for each individual corpus are then concatenated into a single index where all pages from all documents in the corpus are included in a single index. In the same way a Bag of Words model is a simple text representation that disregards word order and only accounts for how many times a word appears, this model could be viewed as a Bag of Pages model that disregards page order and only accounts for the similarity of each page to other pages in the corpus. Page order is disregarded and only similarity of each page to the rest of the pages in the corpus is modeled.

In order to investigate the relationship between scientific consensus and NASA plans a hierarchical approach is used. Although NASA is not a subordinate of the NSF, NASA science plans should inherit information from decadal surveys. This creates informational hierarchy where information from the parent decadal survey corpus flows to the child NASA science plan corpus.

The hierarchical relationship is modeled by creating a baseline of parent corpus documents which in this case is the decadal surveys. This baseline is computed by calculating a simple mean of page vectors constituting the parent corpus.

Figure 2 is a simplified representation of the contextual distance model used. X_1 and X_2 each represent a dimension used to compare the documents thus simplifying the high dimensionality space of 1532 dimensions into just two dimensions in order to visualize the concept.

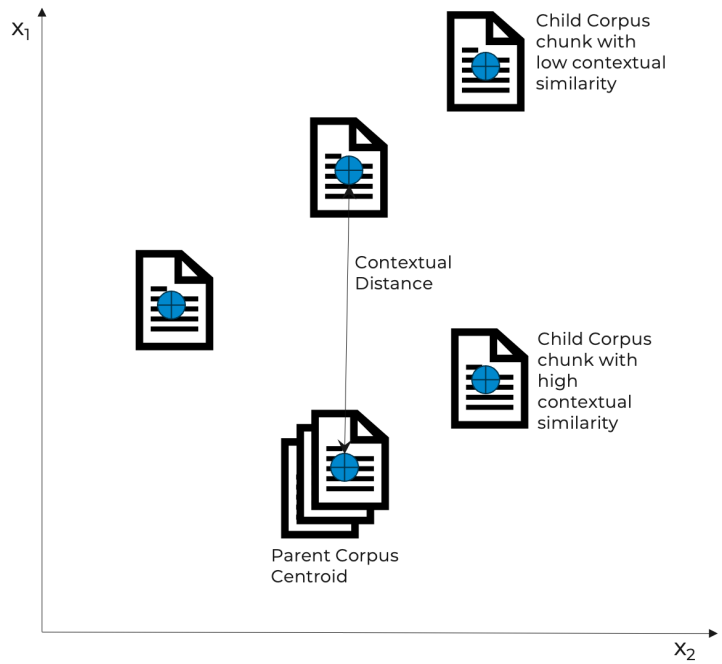

Figure 2: Simplified Contextual Distance Model

The distance of each page in the NASA plan is calculated from the decadal survey centroid. Cosine similarity was chosen to calculate the distance between documents due to the use of cosine similarity in the training of the original embeddings model.

Selection of data for the model required some compromise which is explained in the next section.

3. Data

3.1. Decadal Surveys

The National Research Council (NRC) of the Academies has conducted decadal surveys at approximately a 10 year cadence since 1964. Decadal surveys typically require 2 years to complete each survey [3]. Until 2003, decadal surveys were focused on Astronomy and Astrophysics. However since then, Decadal surveys are listed into the following 5 categories: Astrophysics, Planetary, Heliophysics, Earth, and a final category of Biological and Physical Sciences.

The purpose of decadal surveys is to reach consensus on science priorities for the next decade, while aligning with the executive branch initiatives and adhering to fiscal budget constraints. Science community stakeholders in the decadal surveys include NASA, NSF, DOE, NOAA, and USGS. Congress, the Office fo Management and Budget, and other executive branch agencies use decadal surveys to evaluate budgetary plans. Given the magnitude of impact of the studies, survey committees consist of experienced, active, and accomplished leaders in their respective fields [3].

Decadal surveys for this report were sourced directly from the National Academies Press website [27]. NASA also lists the most recent Decadal Surveys on it's Science Mission Directorate website [28].

The distance of science plan pages is measured from the centroid of the decadal survey corpus. This was necessary because any single decadal survey covers only one of the NASA Science Mission Directorates while NASA Science Plans cover all 5 Science Mission Directorates. The centroid (median) of the 2001-2007 decadal surveys was chosen as those surveys cover 4 of the 5 SMDs. This eliminates Biological and Physical Sciences from the reference centroid because the first decadal survey for this SMD was not released until 2011. Including this survey would cause 3 of the 9 NASA science plans to occur after the last document in the decadal survey corpus thereby causing temporal leakage.

3.2. Science Strategy

NASA Science plans define NASA Science strategy and cross all 5 decadal survey categories to provide guidance for each division of the SMD.

NASA Science plans have two distinct sources. Three of the plans in the corpus are created as NASA Strategic Plans, signed by the NASA Administrator, and seven are Science Mission Directorate (SMD) Science Plans, signed by the Associate Administrator of the Science Mission Directorate[29] [30] [31] [32] [33] [34] [35] [36] [37] [38].

NASA Science Mission Directorate has a web page devoted to science strategy containing SMD Science Plans, NASA Strategic Plans, and accompanying documentation for most years beginning in 2007 [39].

The divisions of the SMD closely align to the decadal surveys and consist of 6 divisions reporting to the Deputy Associate Administrator [40]. Four of the divisions are represented in Table 1. Joint Agency Satellite Division and Biological and Sciences Division are not mapped to the decadal surveys because Joint Agency Satellite has no corresponding decadal surveys and

Biological and Physical Sciences first survey occurs after the first available science plan and was removed to avoid temporal leakage from science plans affecting decadal surveys.

3.3. Matching Surveys with Strategy to measure Context Similarity

Four Decadal Surveys published between 2001 and 2007 were chosen to determine if decadal survey effects are observable on NASA Science Plans using semantic similarity. This reduction has two effects on our data sample. First it reduces the data to points in time prior to the first NASA Science Plan analyzed in the report. Second it creates a sample that represents a cross section matching the scope of NASA Science Plans.

The sample of Decadal Surveys creates a baseline to observe semantic drift of NASA plans that happens after decadal surveys are published. Semantic drift is defined here as the rate of separation of one corpus of text from another over time. The surveys used in this analysis along with the year published and corresponding NASA SMD Division the survey relates to is shown in Table 1. For a complete table of surveys see Appendix A.

Year	**Title**	**Corresponding SMD Division**
2001	Astronomy and Astrophysics for the New Millennium	Astrophysics
2003	The Sun to the Earth—and Beyond: A Decadal Research Strategy in Solar and Space Physics	Heliophysics
2003	New Frontiers in the Solar System: An Integrated Exploration Strategy	Planetary Science
2007	Earth Science and Applications from Space: National Imperatives for the Next Decade and Beyond	Earth Science

Table 1: Decadal Surveys Used in Analysis [27, 39]

4. Analysis and Results

The distance between decadal survey and science plans is measured using cosine similarity. The baseline of decadal surveys is assigned a distance value of 0. A perfectly aligned page would have a distance of 0 and lie directly on

the axis. Individual pages of NASA plans are represented by points shown in Figure 3. Finally the median similarity of the NASA plan pages is represented by the line plot.

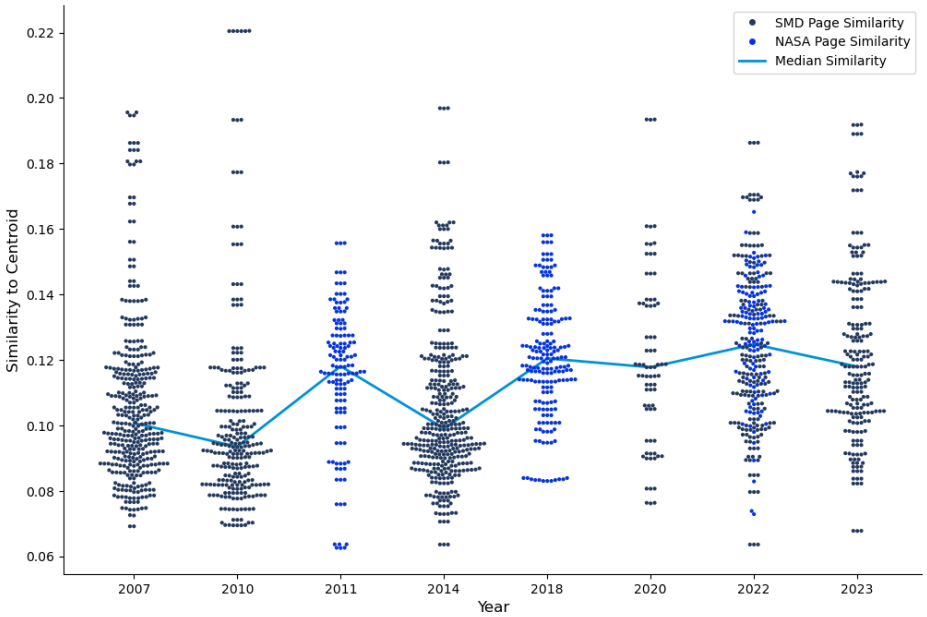

Figure 3: NASA Science Plan Similarity to Decadal Surveys

We can observe two patterns from Figure 3. First the median similarity of the NASA plans in relation to decadal surveys is decreasing over time. Second there is a difference between NASA led plans and SMD led plans as shown by the different colors representing the pages in each corpus. SMD led plan pages tend to be closer to the decadal survey centroid.

5. Discussion and Future Work

The decreased alignment over time between NASA plans and decadal surveys likely has many causal factors. In addition to decadal surveys NASA must have many other competing influences in science plans. We can conjecture that the decreased alignment may be a result of changes in consensus as surveys are updated, changes in executive branch priorities, changes in congressional funding, or changes in operational realities. This introduces multiple vectors that are not accounted for in an analysis that focuses on

decadal surveys and time. The limited amount of data due to the once a decade periodicity of survey publication limits the conclusions that can be drawn.

The analogous results that are observable provide encouragement that measuring the change in semantic similarity may be a useful analysis methodology and provides several areas for further study. This particular study could be expanded by categorizing decadal surveys into the 5 SMD divisions and exploring a more fine grained analysis of each scientific community. As a general approach, cross corpus contextual similarity analysis may be useful in other other areas where cross organizational alignment is a concern. The approach could be extended by comparing page level, or smaller pieces of text across corpora by means of clustering algorithms. Optimization of architecture could also be explored by optimizing for embeddings models and hyperparameters.

Appendix A. Complete List of Decadal Surveys

A complete list of Decadal Surveys is given in Table A.2. The table also incudes a Lessons Learned and Best Practices report conducted as a review of decadal surveys conducted in 2015. For researchers interested in learning more about this is a great resource [3].

Year	Title	Corresponding SMD Division

Table A.2: NASA Science Mission Directorate Decadal Surveys

Appendix B. File Name Metadata

This section details the file name convention used in this analysis and is provided to aid in future work. It is available at TODO: PUBLIC REPO.

Decadal file names: Follow a `yyyy-DS-Category-####.pdf` format where `####` is the National Academies document number. `DS` is used to categorize all decadal surveys. `MA` replaces `DS` for Midterm Assessments, and `SP` is used for the Special Publication in 2015 that identified lessons learned.

Science plan file names: Follow a `yyyy_SSP_Nasa_File_Name.pdf` format. `SSP` represents Science mission directorate Science Plans. This is replaced with `AD` to indicate Additional Documentation, `NSP` to indicate NASA Science Plan, or `AD` to indicate additional documentation present on the SMD website.
